CERTIFIED TRANSLATION

Yuka NAKAMURA residing at c/o SUGIURA PATENT OFFICE,
7th floor, Ikebukuro Park Bldg., 49-7, Minami Ikebukuro
2-chome, Toshima-ku, Tokyo, JAPAN, declares:

(1) that she knows well both the Japanese and English
languages;

(2) that she translated Japanese Application 11-165070 from
Japanese to English;

(3) that the attached English translation is a true
and correct translation of the above-identified Japanese
Application to the best of her knowledge and belief; and

(4) that all statements made of her own knowledge
are true and that all statements made on information and
belief are believed to be true, and further that these
statements are made with the knowledge that willful false
statements and the like are punishable by fine or
imprisonment, or both, under 18 USC 1001, and that such
false statements may jeopardize the validity of the
application or any patent issuing thereon.

[Title of Document] Specification

[Title of the Invention] Camera Apparatus Having
Communicating Device

[Scope of Claims for a Patent]

5 [Claim 1]

A camera apparatus having a communicating
device for transmitting a video signal photographed and
processed by a camera or a video signal temporarily
recorded in a record medium to a remote location,

10 comprising:

connecting means for connecting a plurality
of different communication lines;

15 setting and inputting means for designating
one of the plurality of different communication lines
and setting a transmission condition;

controlling means for determining whether or
not the video signal is transmissible to the remote
location with the transmission rate of the designated
communication line corresponding to an output signal of
20 said setting and inputting means and generating control
information when the video signal is transmissible; and

signal processing means for processing a
transmission signal for the designated communication
line corresponding to the control information supplied
25 from said controlling means.

[Claim 2]

The camera apparatus as set forth in claim 1,

further comprising:

displaying means for displaying information corresponding to the determined result of said controlling means.

5 [Claim 3]

The camera apparatus as set forth in claim 1 or 2, further comprising:

10 data compressing means for compressing the video signal photographed and processed by the camera or the video signal temporarily recorded in the record medium under the control of said controlling means and supplying the compressed video signal to said signal processing means.

[Detailed Description of the Invention]

15 [0001]

[Technical Field to which the Invention belongs]

The present invention relates to a camera apparatus having a communicating device that performs a signal process for video data and audio data
20 corresponding to the transmission capacity of a communication line suitable for a signal transmission of news materials and so forth to a broadcasting station and so forth.

[0002]

25 [Prior Art]

Data rate of high definition video data of the current television broadcasting systems (NTSC and

PAL systems) is for example 270 Mbps (including a blanking portion). Thus, to transmit video data (and/or audio data) that is output from a camera, a communication line having a sufficient transmission capacity is required. When such a communication line is not used, the video data and audio data should be compressed on the transmitting side. The compressed video data and audio data should be decompressed on the receiving side. Examples of the data compressing standards are motion JPEG (Joint Photographic Expert Group), MPEG (Moving Picture Expert Group), and MPEG-2.

[0003]

When news materials photographed and recorded by a camera apparatus or the like at site are transmitted to a broadcasting station, a large scale relaying facility using for example a satellite line or a microwave line is required. Alternatively, a record medium on which news materials have been recorded should be removed from the camera and delivered to the broadcasting station.

[0004]

[Problem to be solved by the Invention]

However, when video data and audio data that are not compressed are transmitted using a communication line, since the line renting fee is expensive, this method is unpractical. Thus, it is difficult to directly transmit raw video data to the

broadcasting station. On the other hand, when a record medium is delivered to the broadcasting station, the immediacy and mobility are insufficient. Whenever video data and audio data that are compressed are transmitted, if a transmission line is selected, the compression rate should be changed corresponding to the transmission capacity of the selected transmission line.

[0005]

An object of the present invention is to provide a camera apparatus having a communicating device that can be connected to a plurality of different communication lines and that can perform a signal process corresponding to the selected communication line and thereby quickly and effectively transmit data.

[0006]

[Means for Solving the Problem]

To solve the above-described problem, a first aspect of the present invention is a camera apparatus having a communicating device for transmitting a video signal photographed and processed by a camera or a video signal temporarily recorded in a record medium to a remote location, comprising a connecting means for connecting a plurality of different communication lines, a setting and inputting means for designating one of the plurality of different communication lines

and setting a transmission condition, a controlling means for determining whether or not the video signal is transmissible to the remote location with the transmission rate of the designated communication line corresponding to an output signal of the setting and inputting means and generating control information when the video signal is transmissible, and a signal processing means for processing a transmission signal for the designated communication line corresponding to the control information supplied from the controlling means.

[0007]

According to the present invention, when the transmission condition has been set, the controlling means determines whether or not a desired signal can be transmitted at the transmission rate of a selected communication line. When the controlling means has determined that the desired signal cannot be transmitted, the controlling means generates information of the determined result and supplies it to the displaying means. When the controlling means has determined that the desired signal can be transmitted with a partial change of the transmission condition, the controlling means generates information for prompting the user to change the transmission condition and supplies it to the displaying means. When the controlling means has determined that the desired

signal can be transmitted, the controlling means generates information of the determined result and supplies it to the displaying means. When the controlling means has determined that the desired signal can be more effectively transmitted with a partial change of the transmission condition, the controlling portion generates information for prompting the user to change the transmission condition and supplies it to the displaying means. When the controlling means has determined that the desired signal can be transmitted and the user has performed a predetermined operation, the controlling means generates control information for controlling each portion so as to effectively perform the transmitting process corresponding to the transmission capacity of the selected communication line. Thus, the user can easily perform various settings corresponding to the information displayed on the displaying means. In addition, in the real transmitting process, the signal can be quickly and effectively transmitted.

[0008]

[Embodiment of the Invention]

Next, with reference to the accompanying drawings, an embodiment of the present invention will be described. Fig. 1 shows the overall structure of the embodiment of the present invention. As shown in Fig. 1, according to the embodiment of the present

invention, a camera portion 1 and a communicating portion 2 are integrated.

[0009]

5 The camera portion 1 comprises an image pickup portion 11, a camera signal processing portion 12, a memory 13, and a VTR portion 14. An object image is photographed by the image pickup portion 11. The photographed picture is converted into an electric signal by a CCD. The image pickup portion 11 generates
10 an image signal corresponding to the electric signal and supplies the image signal to the camera signal processing portion 12.

[0010]

15 The camera signal processing portion 12, the memory 13, and the VTR portion 14 are connected through a bus so that data can be exchanged thereamong. The camera signal processing portion 12 performs a white balance adjusting process, a contour emphasizing process, and a gamma compensating process for the image
20 signal supplied from the image pickup portion 11, performs a matrix converting process for the image signal, and generates a digital video signal and an analog video signal. When necessary, the camera signal processing portion 2 supplies the digital video signal
25 and the analog video signal to the memory 13 or the VTR portion 14 so as to store or record these signals thereto. The analog video signal generated by the

camera signal processing portion 12 or the analog video signal stored in the memory 13 or recorded in the VTR portion 14 is supplied to the communicating portion 2 through a terminal 3. On the other hand, the digital video signal generated by the camera signal processing portion 12 or the digital video signal stored in the memory 13 or recorded in the VTR portion 14 is supplied to the communicating portion 2 through a terminal 4. The camera portion 1 also has an audio signal processing portion (not shown). The audio signal processing portion supplies an analog audio signal to the communicating portion 2 through the terminal 3. On the other hand, the audio signal processing portion supplies a digital audio signal to the communicating portion 2 through the terminal 4.

[0011]

The communicating portion 2 comprises an A/D converter 21, a rate converter 22, a compressing circuit 23, a VTR compressing circuit 24, a switching circuit 25, a transmission signal processing portion 26, a microcomputer 27, a communication interface 28, a displaying portion 29, an operation inputting portion 30, and three connectors 31, 32, and 33. The analog video (and/or audio) signal supplied through the terminal 3 is supplied to the A/D converter 21. On the other hand, the digital video (and/or audio) signal supplied through the terminal 4 is supplied to the rate

converter 22 and the switching circuit 25.

[0012]

5 The A/D converter 21 samples the analog video
(and/or audio) signal supplied from the camera portion
1, quantizes the sampled signal, and converts the
quantized signal into a digital video (and/or audio)
signal corresponding to control information supplied
from the microcomputer 27. The resultant digital video
(and/or audio) signal supplied from the A/D converter
10 21 is supplied to the compressing circuit 23, the VTR
compressing circuit 24, and the switching circuit 25.

[0013]

15 The rate converter 22 converts the sampling
rate of the digital video (and/or audio) signal
supplied from the camera portion 1 to that for the
compressing circuit 23 and the VTR compressing circuit
24 corresponding to control information supplied from
the microcomputer 27. The resultant digital video
(and/or audio) signal with the predetermined sampling
20 frequency supplied from the rate converter 22 is
supplied to the compressing circuit 23, the VTR
compressing circuit 24, and the switching circuit 25.

[0014]

25 The compressing circuit 23 compresses the
digital video (and/or audio) signal supplied from the
A/D converter 21, the digital video (and/or audio)
signal supplied from the rate converter 22, or the

digital video (and/or audio) signal supplied from the terminal 4 corresponding to control information supplied from the microcomputer 27 in such a manner that the compression rate is variable. Examples of the compressing process (standards) are motion JPEG, MPEG, and MPEG-2. The compressing circuit 23 generates a first compression signal and supplies it to the switching circuit 25.

[0015]

The VTR compressing circuit 24 compresses the digital video (and/or audio) signal supplied from the A/D converter 21, the digital video (and/or audio) signal supplied from the rate converter 22, or the digital video (and/or audio) signal supplied from the terminal 4 corresponding to control information supplied from the microcomputer 27 in the same compressing method as a digital VTR used on the receiving side (receiving device). Thus, the VTR compressing circuit 23 can use various compressing methods for conventional VTRs. A second compression signal generated by the VTR compressing circuit 23 is supplied to the switching circuit 25.

[0016]

The first compression signal generated through the compressing circuit 23, the second compression signal generated through the VTR compressing circuit 24, the digital video (and/or

audio) signal supplied from the A/D converter 21, the digital video (and/or audio) signal supplied from the rate converter 22, and the digital video (and/or audio) signal directly supplied from the terminal 4 are
5 supplied to the switching circuit 25. The switching circuit 25 selects one of these digital video (and/or audio) signals corresponding to control information supplied from the microcomputer 27. The signal selected by the switching circuit 25 is supplied as an
10 output signal thereof to the transmission signal processing portion 26.

[0017]

The transmission signal processing portion 26 comprises a parallel/serial converting circuit, a
15 scrambler, an encoder, and a modulating circuit. The transmission signal processing portion 26 performs an encoding process, a modulating process, and so forth corresponding to control information supplied from the microcomputer 27 in such a manner that these processes
20 comply with the standard of a selected communication path and generates a transmission signal. In reality, the transmission signal processing portion 26 converts a parallel signal supplied from the switching circuit 25 into a serial signal, scrambles the serial signal,
25 encodes the scrambled signal, and modulates the encoded signal. The transmission signal processing portion 26 supplies the generated transmission signal to the

communication interface 28.

[0018]

5 The communication interface 28 has an output
driver and so forth. The communication interface 28
converts the transmission signal supplied from the
transmission signal processing portion 26 corresponding
to control information supplied from the microcomputer
27 in such a manner that an output waveform of the
transmission signal complies with the standard of the
10 selected communication line. The communication
interface 28 supplies the converted signal to one of
the three connectors 31, 32, and 33 designated by the
microcomputer 28. In other words, the communication
interface 28 converts the transmission signal into an
15 output signal that complies with the electric
specifications of the selected communication line.

[0019]

20 The three connectors 31, 32, and 33 comply
with mechanical specifications corresponding to the
standards of the connected communication lines. The
connector 31 is connected to a line a. The connector
32 is connected to a line b. The connector 33 is
connected to a line c. Thus, the transmission output
signal supplied from the communication interface 28 is
25 transmitted to one of the communication lines a, b, and
c through one of the three connectors 31, 32, and 33.
Examples of the communication lines are a telephone

line, an ISDN line, an ATM line, a public line (such as Internet), and a dedicated line.

[0020]

5 As described before, the displaying portion
29 and the operation inputting portion 30 are connected
to the microcomputer 27 that controls each portion of
the communicating portion 2. The operation inputting
portion 30 has a plurality of setup switches, a ten key
pad, and so forth. When the user operates these setup
10 switches and the ten key pad, the operation inputting
portion 30 generates detection information
corresponding to the operation state and supplies the
detection information to the microcomputer 27. The
displaying portion 29 comprises for example an LED, an
15 LCD panel, and a driving circuit. The displaying
portion 29 displays various types of information
corresponding to information supplied from the
microcomputer 29.

[0021]

20 The microcomputer 27 has a memory (not
shown). The microcomputer 27 monitors the operation
state of the operation inputting portion 30
corresponding to the detection information. When
necessary, the microcomputer 27 generates information
and supplies it to the displaying portion 29. When a
25 transmission condition is set, the microcomputer 27
determines whether or not a desired video (and/or

audio) signal can be transmitted with the transmission rate of the selected communication line. When the microcomputer 27 has determined that the desired signal cannot be transmitted, the microcomputer 27 causes the displaying portion 29 to display the determined result. When the microcomputer 27 has determined that the desired signal can be transmitted with a partial change of the transmission condition, the microcomputer 27 prompts the user for the change of the transmission condition. When the microcomputer 27 has determined that the desired signal can be transmitted, the microcomputer 27 causes the displaying portion 29 to display the determined result. When the microcomputer 27 has determined that the desired signal can be more effectively transmitted with a partial change of the transmission condition, the microcomputer 27 prompts the user for a change of the transmission condition. When the user has performed a predetermined operation with the operation inputting portion 30 for starting the transmitting process, the microcomputer 27 reads various types of information from the memory corresponding to the detection information supplied from the operation inputting portion 33, generates control information, and supplies the generated control information to each portion of the communicating portion 2. In other words, the microcomputer 27 centrally controls each portion of the transmission

portion 2 so that the transmitting process can be effectively performed corresponding to the transmission capacity of the selected communication line. Before the transmitting process is performed, the memory of the microcomputer 27 has stored setup information such as the transmission rate and error rate of the selected communication line. In addition, the memory has stored various types of information corresponding to the communication standard necessary for performing various determining processes and various types of information necessary for generating information displayed on the displaying portion 29.

[0022]

In Fig. 1, reference numeral 5 is a receiving device. The receiving device 5 comprises three connectors 51, 52, and 53, a communication interface 54, a reception signal processing portion 55, a microcomputer 56, a displaying portion 57, an operation inputting portion 58, a VTR parallel interface 59, a VTR serial interface 60, a decompressing circuit 61, a VTR decompressing circuit 62, a switching circuit 63, a D/A converter 64, a rate converter 65, and an external interface circuit 66.

[0023]

The three connectors 51, 52, and 53 comply with mechanical specifications corresponding to standards of connected communication lines. The

connector 51 is connected to the line a. The connector 52 is connected to the line b. The connector 53 is connected to the line c. A transmission signal transmitted from the communicating portion 2 is supplied to the communication interface 54 through one of the three connectors 51, 52, and 53.

[0024]

The communication interface 54 has an input driver and so forth. The communication interface 54 performs an inverse waveform process of the transmitting side for the input transmission signal, converts the communication signal into a reception signal for the reception signal processing portion 55, and supplies the reception signal to the reception signal processing portion 55 corresponding to control information supplied from the microcomputer 56.

[0025]

The reception signal processing portion 55 comprises a demodulating circuit, a decoder, a descrambler, and a serial/parallel converting circuit. The reception signal processing portion 55 performs a demodulating process and a decoding process for the reception signal processed on the transmitting side corresponding to control information supplied from the microcomputer 56 and generates a first compression signal, a second compression signal, or a digital video (and/or audio) signal. In reality, the reception

signal processing portion 55 demodulates the reception signal and then decodes the demodulated signal.

Thereafter, the reception signal processing portion 55 descrambles the decoded signal and converts the

5 descrambled signal as a serial signal into a parallel signal. The first compression signal restored by the reception signal processing portion 55 is supplied to the decompressing circuit 61. The second compression signal restored by the reception signal processing
10 portion 55 is supplied to the VTR decompressing circuit 62, the VTR parallel interface 59, and the VTR serial interface 60. The non-compressed digital video (and/or audio) signal restored by the reception signal processing portion 55 is supplied to the switching
15 circuit 63.

[0026]

The decompressing circuit 61 decompresses the first compression signal supplied from the reception signal processing portion 55 corresponding to control
20 information supplied from the microcomputer 56 in such a manner that the decompressing process complies with the compressing process performed on the transmitting side and outputs a digital video (and/or audio) signal. The digital video (and/or audio) signal decompressed by
25 the decompressing circuit 61 is supplied to the switching circuit 63.

[0027]

The VTR decompressing circuit 62 decompresses the second compression signal supplied from the reception signal processing portion 55 corresponding to control information supplied from the microcomputer 56 in such a manner that the decompressing process complies with the compressing process performed on the transmitting side and outputs a digital video (and/or audio) signal. The digital video (and/or audio) signal decompressed by the decompressing circuit 62 is supplied to the switching circuit 63.

[0028]

The digital video (and/or audio) signal is directly supplied from the reception signal processing portion 55 to the switching circuit 63. The digital video (and/or audio) signal is supplied from the decompressing circuit 61 to the switching circuit 63. The digital video (and/or audio) signal is supplied from the VTR decompressing circuit 62 to the switching circuit 63. The switching circuit 63 selects one of the three input signals corresponding to control information supplied from the microcomputer 56. The signal selected by the switching circuit 63 is supplied as an output signal thereof to the D/A converter 64, the rate converter 65, and the external interface circuit 66.

[0029]

When necessary, the D/A converter 64 converts

the digital video (and/or audio) signal supplied from the switching circuit 63 as a digital signal into an analog signal corresponding to control information supplied from the microcomputer 56. The analog video (and/or audio) signal converted by the D/A converter 64 is obtained through an output terminal 8.

[0030]

When necessary, the rate converter 65 converts the sampling rate of the digital video (and/or audio) signal into that for the signal process of a circuit connected to an output terminal 9 corresponding to control information supplied from the microcomputer 27. The digital video (and/or audio) signal with the sampling frequency converted by the rate converter 22 is obtained through the output terminal 9.

[0031]

The external interface circuit 66 is a digital interface for transmitting a digital video (and/or audio) signal to an external device. The external interface circuit 66 performs a process corresponding to control information supplied from the microcomputer 27. An output signal of the external interface circuit 66 is obtained through an output terminal 10 and supplied to an external device.

[0032]

A first VTR that records a digital video (and/or audio) signal is connected to an output

terminal 6. The VTR parallel interface 59 performs an interfacing process for the second compression signal supplied from the reception signal processing portion 55 corresponding to control information supplied from the microcomputer 56. An output signal of the VTR parallel interface 59 is obtained through the output terminal 6 and supplied to the first VTR. A second VTR is connected to an output terminal 7. The VTR serial interface 60 performs an interfacing process for the second compression signal supplied from the reception signal processing portion 55 corresponding to control information supplied from the microcomputer 56. An output signal of the VTR serial interface 60 is obtained through the output terminal 7 and supplied to the second VTR.

[0033]

The displaying portion 57 and the operation inputting portion 58 are connected to the microcomputer 56 that controls each portion of the receiving device 5. The operation inputting portion 58 has a plurality of setup switches, a ten key pad, and so forth. When the user operates these setup switches and the ten key pad, the operation inputting portion 58 generates detection information corresponding to the operation state and supplies the detection information to the microcomputer 56. The displaying portion 57 comprises for example an LED, an LCD panel, and a driving

circuit. The displaying portion 57 displays various types of information corresponding to information supplied from the microcomputer 56.

[0034]

5 The microcomputer 56 has a memory (not shown). The microcomputer 56 monitors the operation state of the operation inputting portion 58 corresponding to the detection information. When the user performs a predetermined operation with the operation inputting portion 58, the microcomputer 56 reads various types of information from the memory corresponding to the detection information supplied from the operation inputting portion 58, generates control information for each portion of the receiving device 5, and supplies the generated control information to each portion of the receiving device 5 so that the microcomputer 5 centrally manages each portion of the receiving portion 5. In addition, the microcomputer 56 generates information displayed on the displaying portion 57. The memory of the microcomputer 56 stores various types of information of communication standards.

[0035]

25 According to the embodiment of the present invention, the communicating portion 2 has only the transmitting function. When the communicating portion 2 performs a bidirectional communication, the

communicating portion 2 has the structure of the receiving device 5 so as to transmit and receive signals.

[0036]

5 Next, a transmitting process for transmitting a video (and/or audio) signal according to the embodiment of the present invention will be described. Before the signal is transmitted, one of the communication lines a, b, and c is selected. The
10 selected line is connected to a relevant connector. Thereafter, the user operates the operation inputting portion 30 and input various types of data of the selected communication line. When the transmission capacity of the selected communication line is unknown,
15 the structure of the receiving device 5 may be disposed in the communicating portion 2 so as to transmit and receive signals between the communicating portion 2 and the receiving device 5. Thus, the transmission rate and error rate of the selected communication line will
20 be automatically measured and obtained.

[0037]

 After various types of data of the selected communication line are input, all or part of the following items are input corresponding to information
25 displayed on the displaying portion 29.

[0038]

(1) A direct transmission mode or an

indirect transmission mode is selected. In the direct transmission mode, a signal that is supplied from the image pickup portion 11 is transmitted on real time basis. In the indirect transmission mode, a signal
5 recorded in the VTR 14 or stored in the memory 13 is read and transmitted.

[0039]

(2) When the indirect transmission mode (for reading a signal from the VTR portion 14 or the memory
10 13 and transmitting the signal) has been selected, a start point and an end point for transmitting a signal are input.

[0040]

(3) When the indirect transmission mode (for reading a signal from the VTR portion 14 or the memory
15 13 and transmitting the signal) has been selected, a transmission time period is input.

[0041]

(4) When a signal is compressed, a
20 compression method is selected.

[0042]

(5) The sampling rate of the digital video (and/or audio) signal is designated. The type of the picture signal, the number of frames to be transmitted,
25 and so forth are input.

[0043]

When the items (1) to (5) have been selected

and input, the microcomputer 27 determines whether or not the desired signal can be transmitted with the transmission rate of the selected communication line. When the microcomputer 27 has determined that the
5 desired signal cannot be transmitted, the microcomputer 27 causes the displaying portion 29 to display the determined result. When the microcomputer 27 has determined that the desired signal can be transmitted with a partial change of the transmission condition,
10 the microcomputer 27 prompts the user for the change of the transmission condition. When the microcomputer 27 has determined that the desired signal can be transmitted, the microcomputer 27 causes the displaying portion 29 to display the determined result. When the
15 microcomputer 27 has determined that the desired signal can be more effectively transmitted with a partial change of the transmission condition, the microcomputer 27 prompts the user for a change of the transmission condition. After the user selects and inputs data
20 corresponding to information displayed on the displaying portion 57 and then performs a predetermined operation for starting the transmitting process, the desired signal is transmitted.

[0044]

25 When data of the above-described items (1) to (5) is selected and input, the transmitting process can be more effectively performed. In reality, when a

signal of a news material is reproduced from a tape and transmitted, a portion that is not used in a broadcast program is designated with a time code and compressed with a high compression rate. A portion that is used in a broadcast program is designated with a time code and compressed with a low compression rate. Thus, a video signal with high quality can be transmitted from the site to the broadcasting station. Thus, the transmission line can be effectively used.

[0045]

Next, real examples of the transmitting process according to the embodiment of the present invention will be described with reference to Figs. 2A, 2B, 2C, and 2D. The data rate of high definition video data of the current television broadcasting systems (NTSC and PAL systems) is for example 270 Mbps (including a blanking portion). When a video signal that is output from the image pickup portion of the camera portion 1 is transmitted through a communication line with a transmission rate of 500 Mbps as shown in Fig. 2A, the microcomputer 27 controls each portion of the communicating portion 2 so that the communicating portion 2 transmits a non-compressed signal. Thus, the receiving device 5 does not need to perform the decompressing process for the received signal.

[0046]

When a video signal that is output from the

image pickup portion 1 is transmitted through a communication line with a transmission rate of 2 Mbps as shown in Fig. 2B, the microcomputer 27 controls each portion of the communicating portion 2 so that the communicating portion 2 compresses the video signal with a compression rate of 1/135. The receiving device 5 performs a decompressing process for the received signal.

[0047]

When a VTR is connected to the receiving device 5 as shown in Fig. 2C and a video signal that is output from the image pickup portion of the camera portion 1 is transmitted through a communication line with a transmission rate of 50 Mbps, the microcomputer 27 controls each portion of the communicating portion 2 so that the communicating portion 2 compresses the video signal in a predetermined format for a VTR of the receiving device 5. The VTR of the receiving device 5 records the received signal.

[0048]

When a video (and/or audio) signal of a news material for three minutes is reproduced from a VTR or the like and transmitted through a communication line with a transmission rate of 50 kbps as shown in Fig. 2D, the video (and/or audio) signal is compressed with a large compression rate and then transmitted. In reality, when the video (and/or audio) signal is

reproduced from the VTR, the transmission rate is 30 Mbps. The video (and/or audio) signal is compressed with a compression rate of 1/100 and transmitted in 18 minutes. A required portion of the video (and/or audio) signal for three minutes is designated. The designated portion is not compressed. The non-compressed signal is transmitted. In reality, when only five seconds of the video (and/or audio) signal for three minutes are designated, data with a transmission rate of 30 Mbps reproduced from the VTR is transmitted in 50 minutes.

[0049]

[Effect of the Invention]

According to the present invention, when the transmission condition is set, the controlling means determines whether or not a desired signal can be transmitted with the transmission rate of the selected communication line. The displaying portion displays information corresponding to the determined result. When the transmitting process is actually performed, the controlling means generates control information and supplies each portion of the communicating portion so that each portion effectively performs the transmitting process. Thus, according to the present invention, the user can easily perform various settings with reference to information displayed on the displaying portion. In the real transmitting process, a signal can be quickly

and effectively transmitted. In addition, according to the present invention, since communication lines can be effectively used and the compression rate can be partly changed, the cost of the signal transmission can be reduced.

Block diagram showing the overall structure of an embodiment of the present invention.

[Fig. 2]

Schematic diagrams for explaining operations of the embodiment of the present invention.

[Description of Reference Numerals]

1 ... Camera portion, 2 ... Communication portion, 11 ... Image pickup portion, 12 ... Camera signal processing portion, 13 ... Memory, 14 ... VTR portion, 21 ... A/D converter, 22 ... Rate converter, 23 ... Compressing circuit, 24 ... VTR compressing circuit, 25 ... Switching circuit, 26 ... Transmission signal processing portion, 28 ... Communication I/F, 29 ... Displaying portion, 30 ... Operation inputting portion, 31, 32, 33 ... Connector

[Title of Document] Abstract

[Abstract]

[Subject]

5 This invention is to provide transmitting the
data smoothly and effectively by easy-performing a
various kind of setting.

[Solving means]

10 A microcomputer 27, a transmission signal
processing portion 26, and operation inputting portion
30, and a displaying portion 29 contains in the device.
When the transmission condition is setup, in the
microcomputer 27, the microcomputer 27 determines
whether or not a desired video signal can be
transmitted with the transmission rate of the selected
15 communication line. A various kind of setting can be
easily performed by displaying on the displaying
portion 29 corresponding to the determined result. In
the addition, if it is determined as the data that can
be possibly transmitted and the transmission operation
20 is actually initiated, the control information is
generated for controlling each of the transmission
process effectively corresponding to the transmission
ability of using the communication line. Besides, this
control information is supplied to each portion, and
25 the data can be transmitted quickly and effectively.
